

Warts

Often referred to as plantar warts. These can be found anywhere on the sole of the foot or the toes but tend to produce symptoms in areas of pressure and friction. The virus that causes warts, infects the superficial layer of the skin, producing a thickened callus-like growth that can become quite tender.

Although warts characteristically resolve spontaneously, they occasionally require treatment when symptomatic. Warts can either be frozen (cryotherapy), treated with powerful topical applications (chemotherapy), or can be removed surgically. The treatment of choice is made by your Podiatrist, depending on the size and area that is affected.
